Abstract

This paper analyses the fundamentals of the Portuguese crisis. The financial crisis of 2007 worsened and triggered the current Portuguese crisis. We argue that the main problem that the economy is facing is its output stagnation due to a kind of Dutch disease that has created high and increasing levels of indebtedness, low and decreasing levels of saving and has reduced Portuguese competitiveness. Moreover, the existence of a dualist labour market and a new vague of emigration reproduces inefficiency increasing unemployment of younger workers and the supply of human capital abroad funded by the Portuguese taxpayers. Governance problems such as bad public budget governance, lack of transparency and accountability are also at stake and have to be solved to allow the economy to return to its long-run growth path.

Key words: Growth, Debt, Saving, Dutch disease, Unemployment, Budget policy.

JEL: E21, F34, G01, H10, H63.

Introduction

The scope of automatic stabilization is too narrow in the face of a severe recession preceded by a long period of sluggish growth, O'Hara (2011). The elasticity of government receipts with respect to GDP is usually greater than that elasticity of government expenditures. So, in times of an economic recession the automatic deficit tends to increase through government receipts reduction. More aggressive fiscal policies aimed to overcome a severe recession were conducive to greater deficits through government expenditures increases but their efficacy remains controversial Auerbach, Gale and Harris (2010). This was the case mainly for the USA when compared with that of European countries during 2007 crisis. The USA developed more ambitious help plans, nevertheless for the G20 the budget deficit was 1% of GDP in 2007 and 9% in 2009. High values of budget deficits led to a never seen growth of public debt. This growth that most probably has acted as a stability buffer for financial institutions was this time not free of uncommon risks when these institutions were looking for safer assets. Debt accumulation and its downgrading put financial institutions out of the obliged ratios for assets and liabilities, creating a link of causality from state solvency problems to private institutions. Portuguese financial institutions are facing that problem. At the same time, the trade-off between consolidation and stabilization was destroyed for most of the countries in favor of consolidation producing recession episodes, Barrios, Langedijk and Pench (2010).

The main issue faced by Ireland (Gurdgiev, et al. (2011)) during the financial crisis was the

bailing out of Anglo Irish and Irish Nationwide Building Society, which pushed the budget deficit to around 38.5% of GDP in 2010, and it led to an expected sharp rise in public debt from 65.8% of GDP in 2009 to around 126% of GDP in 2011. As for the Portuguese and Greece (Kouretas and Vlamis (2010)) cases the problem was not the bailing out of financial institutions. In Portugal the recent crisis clearly showed problems at two banks that fall in common-criminal law, which were not a consequence of the financial crisis.

At May 3rd, 2011, it was announced the total bailout out of 78 billions Euros for the Portuguese economy. This was the result of negotiations between the Portuguese government with the IMF, European Commission and the European Central Bank following the request for financial aid made by the Portuguese government to the European Commission (EC) on April 6, 2011. As a consequence of the bail out, the Portuguese deficit target is 5.9% of GDP in 2011, and not 4.6% as it was previously agreed with the EC. For the next two years it will be 4.5% and 3% in 2012 and 2013, respectively. Portugal is the third economy asking for financial aid in the Euro area. The program was approved by the European Finance Ministers on May 16, 2011. The IMF will lend at 3.25% a total of €26 billions and the remaining €52 billions will be lent by the European Financial Stabilisation Mechanism and European Financial Stabilisation Fund at an average interest rate of 5.7%.

In this paper we explain the reasons why Portugal has fallen in this calamitous situation. Several factors led to different problems though intertwined that were conducive to this situation. The first problem is the sluggish Portuguese output growth. This problem was due mostly to the lack of structural reforms, namely in the labour market, low levels of human capital of the Portuguese labour force, and the negative impact of globalization that suffered our economy from EU eastern enlargement and China accession to WTO since 2001. The second problem is the result of monetary integration associated with bad policies. The decrease of interest rates after years of inflation uncertainty and high nominal interest rates have created a kind of Dutch disease. The degree of public and private indebtedness reached very high levels, the saving rate experienced a decrease and a dangerous negative trend and price competitiveness deteriorated continuously reducing the rate of output growth. The third problem is the lack of accountability and transparency of political governance.

Based on that framework it is perfectly comprehensible the continuous downgrading of the Portuguese sovereign debt made by rating agencies. Those decisions have had implications in the devaluation of banking assets creating a need of capital strengthening forcing most of the banks to sell participations in other financial and non-financial institutions. Our analysis is consistent with that of the IMF: “The program is built on three strong pillars. First, a set of pro-growth measures aimed at making the country competitive again and creating jobs--especially for the young people of Portugal. Second, a set of ambitious fiscal measures needed to reduce the public debt and deficit, implemented at a pace that is realistic and which allows Portugal the time it needs to demonstrate policy implementation and restore market confidence. Third, a set of measures aimed at ensuring the stability of Portugal’s financial sector.” Strauss-Kahn and Rehn (2011). The paper is organized in eight sections, besides introduction and the conclusion. In the first, “A Brief History of Portuguese Financial Distress” is presented; next we questioned the “Portuguese Government Size” which is followed by the inspection of “The Portuguese Output Stagnation”; in the fourth section we analyse main impacts of the Portuguese “European Integration”; the problem of “Saving and Indebtedness in the Portuguese Economy” was envisaged afterwards; “External Competitiveness of Portuguese Economy” is the topic handled in the sixth section and is followed by a brief characterisation of “Labour Market and Unemployment Behaviour” and finally, in the eight section issues concerning Portuguese “Bad Governance: the problem of off-budgeting practice matters” are envisaged.

1. A Brief History of Portuguese Financial Distress

The Portuguese maritime expansion was so badly managed by the Portuguese King, like Spain with Filipe the Second, that in 1560 (Reinhart and Rogoff (2008) and Reinhart and Rogoff (2009)), 60

years after the arrival to Brazil, Portugal made default of external debts with other European countries in the sense used by the authors of default followed by rescheduling. From 1828 to 1852, five episodes express the vulnerability of the Kingdom's Treasury. In April 1890, Argentina stops payments to creditors and Baring Brothers became insolvent in November 1890. The Baring Brothers was an important source of financing to the Portuguese government. With the Brazilian crisis between January and April of that year, and the persistence of public budgets deficits, currency reserves fall by a half and in May the Portuguese experience of gold standard ended (1854-1891), Santos (2001) and Duarte and Andrade (2011). In 1892 the Portuguese government stops payments and the rescheduling of debts came to an end in 1902. Only 1/3 of total debts were paid, Mata and Valério (1994), in the twenties of the XXth century, external financing of the government was closed, and the last payment associated with this operation was made in 2001. A period of financial instability has characterized the post-war period 1917-1926 with many bank failures. After this period (and until now) the Portuguese economy has not experienced any bank failure. From 1945 to 2007 and in a set of sixty-six countries only Austria, Belgium, Portugal and the Netherlands have escaped banking crises. Even in 1960 when the war in Angola starts and also in 1974 with the Portuguese Revolution there were no signs of bank-run.

From 1926 to 1974, the dictatorial regime that ruled Portugal, segregated the country at the international level. Portugal was admitted to the United Nations only in December 14, 1955 and became a member of the IMF since March 29, 1961. After the declaration of George Marshall at June 5, 1947 the Portuguese government decided not to participate in the Marshall aid, the so-called Economic Recovery Program, Rollo (1994). Portugal participated only in the creation of the Organization for European Economic Co-operation but in September 27, 1948, the Prime Minister Salazar was obliged to demand economic and financial aid from the Marshall Plan. International reserves saw a decrease of 42% from 1946 to 1948, and they were 60% of GNP in 1946 and only 34% in 1948¹, (Banco_de_Portugal (1949) and INE (1959)). As a consequence the Portuguese economy had not benefited from the major part of funds. Nevertheless from 1949 to 1951 were received in Portugal 70 millions of dollars. Public infrastructure and industrialization benefitted from those funds.

In 1960, Portugal faced again an external problem due to a shortage of international reserves but the development of the Portuguese tourism sector and emigrants' remittances, especially from France, solved that problem. After the Carnation Revolution (April 25, 1974), Portugal requested assistance from the IMF (1977/78) , IMF (2011), to solve a urgent problem of public and external deficits, associated with other serious macroeconomic imbalances such as sharp increases in unemployment, pressure from oil prices and a huge inflationary pressure. The first credit tranche arrived in 1977 and the second in 1978. IMF financial help ascended to €111 million at current exchange rate. A second financial aid was requested by Portugal to the IMF in 1983. One again, nothing new occurred, the same known problems emerged: high public and external deficits. The total financing this time was €555 million. Despite the recognized success of these two aid plans (for the first see Schmitt (1981)) external conditions of the Portuguese economy evolved in such a virtuous way that the Portuguese authorities did not need to meet the accorded programs in terms of the agreed instruments.

2. Portuguese Government Size

Are average government indicators pointing out to a Portuguese macroeconomic situation that would evolve to a sovereign debt default?

Table 1. gives information about government size (ratio of expenditures over GDP%) for European Union with 27 members, Euro area with 12 members, that are representatives of a stronger fiscal policy discipline, and Germany and France, the two major members of the Euro area, and the three countries under fiscal and debt stress, Ireland, Greece and Portugal. The ratio of total expenditure of general government over GDP gives information about government size. The

¹ We owe this observation to Professor Manuel Jacinto Nunes.

general government sector comprises central government, state government, local government, and social security funds.

Table 1. Ratio of expenditures to GDP (%)

	Germany	France	Ireland	Greece	Portugal	E27	Euro12
1988-90	43.8	49.3	44.5	41.5	37.0		
1995-97	50.8	54.3	39.0	44.9	41.6	50.1	51.0
2002-04	47.9	53.0	33.4	45.1	43.6	46.9	47.7
2008-10	46.0	55.1	53.0	50.7	48.4	49.4	49.6

Source: AMECO and UTAO (2011) and authors' calculation

Two main conclusions can be drawn from Table 1 above. Portugal and Greece are the countries for which expenditure has been never reduced for the chosen periods and Portugal has a level of expenditure less than the average of E27 and Euro12 and near the value of Germany. Based on this indicator it's difficult to find out an excessive size for Portuguese Government .

Since February 1992 the future members of the European Monetary Union knew the general conditions about deficit and debt values. Table 2. below exhibits the occurrences of excessive deficit and positive budget balance for Euro12, Germany, France, Ireland, Greece and Portugal haven't limit before the current crisis, from 1995 to 2007.

Table 2. Occurrences of Excessive Deficit and Positive Budget Balance

	Excessive Deficit	Positive Budget Balance
EU12	(3) 1995-1996 and 2003	2000
Germany	(6) 1995-1996, 2002-2005	2000
France	(6) 1995-1997, 2002-2204	
Ireland	(0)	1997-2001, 2003-2007
Greece	(13) 1995-2007	
Portugal	(9) 1995-1998, 2001, 2003-2006	

Source: AMECO and UTAO and authors' calculation

A positive balance was registered in 2000 for Euro12 and Germany. For 1997-2001 and 2003-2007, Ireland has registered successive positive budget balances. Germany and France had 6 times deficits greater than 3%. The Euro Area is an example of *moral hazard* creation by its leaders. The assumed Euro authority in these countries is very weak in historical and moral terms (see also Prokopijević (2010)). In Germany the Constitutional amend introduced in 2009 will impose structural budget balances equilibrium at the Federal level in 2016 and at the Länders level in 2020, Federal Ministry of Finance (2009) and Feld and Baskaran (2010).

Very high values for public debt, doubling the limit of 60% for many countries, influenced the recent turmoil in sovereign financial market. At the end of 2010 (UTAO (2011)), the highest level was registered by Greece (142.8%) followed by Italy (119%), Ireland (96.2%) and Belgium (96.8%) and Portugal (93%). The value for the Euro area at 17 was 85.1%, meaning that the Portuguese value is higher but not very far from the average of this area. Notice that Ireland was reducing its level of public debt from 1987 to 2007.

The problem with the Portuguese economy is neither about average values indicators nor about a long term view of fiscal sustainability. Marinheiro (2006) has confirmed sustainability using the conventional unit root and co-integration analysis. But the problem at stake for the Portuguese economy should not be identified with a kind of long term decision by capital markets based on past data. Instead it should be envisaged as a situation of lending rupture created by forward expectations. The same comment applies to the “rule” of the 90% threshold value of debt: being less does not affect growth but greater will have negative implications, Checherita and Rother (2010) and Reinhart and Rogoff (2010). We will try to explain why the Portuguese economy is in a situation of rupture and why the financial aid is a necessity.

3. The Portuguese output stagnation

In order to understand the Portuguese output path we analyse the evolution of the output in terms of growth rates and actual levels for 1960-2010. Considering these two variables we get a more accurate understanding of the evolution of the economy. The Portuguese economy experienced in the past growth rates that are typically of emergent economies. For the period 1969-73, the GDP average growth was 8.2% (Table 3).

Table 3. GDP Growth Rates (%)

1960-64	5.8
1969-73	8.2
1986-90	6.6
1994-98	3.8
2001-10	0.5
2006-10	0.3

Source: Ameco and authors' calculation

In the first years of the European integration (1986-90) the growth rate attained 6.6%, a result in accordance to growth predictions of real convergence since Portuguese real income was only a percentage of the real income of the EU12 economy Duarte and Simões (2002). But Portuguese divergence from EU started in 2001 since growth became anaemic during the last nine years. The growth trend rate for the Portuguese Economy was computed using the H-P filter ($\lambda=100$) as illustrated in Figure 1. below.

Figure 1. Growth trend rate (H-P) for the Portuguese Economy

Source: Ameco and authors' calculation.

To obtain H-P trend values we have used $\lambda=100$ to a new series increased 4 periods by an ARIMA model chosen by the Schwarz criteria. The picture of the Portuguese growth rate decline is very clear. The exception is for the first years following the European integration. The last phase of decline starts in 1999.

But the beginning of this last phase doesn't coincide with the above one if we take the GDP trend (in logs and with a $\lambda=100$, Figure 2.).

Figure 2. GDP H-P Trend

Source: Ameco and authors' calculation

In the figure above output stagnation clearly starts in 2002. Table 4. expresses the actual stagnation of the Portuguese economy.

Table 4. Trend Growth Rates

	Trend Growth Rate
1998-00	2.65
2002-04	1.56
2008-10	1.04

Source: Ameco and authors' calculation

The evidence of output stagnation since 2002 has pushed our analysis further in order to forecast the output trend gap for 2010. Due to the atypical GDP behavior in the period following the Carnation Revolution, we have forecasted the values of GDP trend (H-P) based on 1978 to 2001 for the years 2002 to 2010. The model used for this projection, with trend GDP in logs, includes a constant, a time trend and the lagged value of the dependent variable. The AR1 model allows us to take into account the inertia of output trend evolution. We used the Ki (2009) procedure for R that applies the bias correction of Shaman and Stine (1988) caused by auto-regressive estimations and the correction of Kilian (1998) for the confidence intervals of the forecast, for which were made 1000 bootstrap iterations, to obtain 90% confidence intervals.

The new series for the GDP trend augmented with trend forecast for 2002-2010 (A) and the two series compared (B) are in Figure 3.

Figure 3. GDP Trend Correction (A) & (B)

Source: Ameco and authors' calculation

The existence of sluggish growth is now perfectly obvious (Figure 3. (B)). Roubini (2011) recognises the dependence from growth for the success of the stabilisation program of May 4. For him the lack of growth of the Portuguese economy is the most important problem that the country is faced with.

The usual way of trend calculation hides a grim reality for Portugal what can be seen in the values of output gap (Table 5.).

Table 5. Output gap values in %

	2006	2007	2008	2009	2010
Gap	-0.19	1.16	0.20	-3.43	-3.30
GapC	-8.58	-9.26	-12.26	-17.90	-19.66

Source: Ameco and authors' calculation

By the usual calculation, the negative gap is inexistent in 2008 (0.2%) but by our calculation the gap is 12%. And in 2010 the value is near 20%. This gives a black picture of the Portuguese economy that also has consequences at the level of the budget deficit corrected by output cyclical fluctuations. This applies to the correction based on H-P filter and also based on the production function because this last method depends essentially on that filter in input calculations (European Community (1995) and D'Auria, et al. (2010) in the European Union). If we don't correct the trend in terms of using two trends, an effective one and a desired one the indicators of fiscal policy can be very misleading. Using only the first one we are prone to advise restrictive discretionary fiscal policies while the economy has already substantial positive budget balances, after the correction of cyclical fluctuations by the second (desired) trend.

4. European Integration: inflation convergence and the Dutch disease

The inflation convergence was necessary for the Portuguese euro-area membership. After Carnation Revolution we experienced a process of high and unstable inflation (see Figure 4.). For 1984-85 the average rate of inflation, measured by the CPI, was 21,76%, in 1990-91, it was 11,56 and 2.59% in 1999-2000. So the Portuguese inflation convergence process occurred at a fast speed. From 1977 to 1990 the Portuguese Central Bank (Banco of Portugal) applied a policy of bank credit rationing with a crawling-peg exchange rate policy. In the last years of that reform (1990) there were too much exceptions to the target level of banking credit and it was also recognised the need

to have interest rates and credit reflecting market conditions. So in 1991 the Banco of Portugal started a policy of targeting the value of the exchange rate of the Deutsche Mark, what it was equivalent to a policy of real evaluation of the Portuguese Escudo to control and reduce the inflation rate. This is a policy that presents potential long-run drawbacks that can hamper growth in the future. Rebelo and Vegh (1995) shows that this kind of policy is more efficient in the short run than the conventional monetary policy to the control of inflation but has real greater costs in the long run resulting from the lost of price competitiveness.

Figure 4. Annual Inflation Rate (CPI) from 1973:1 to 2002:4

Source: INE (Portuguese National Statistical Institute)

In order to estimate the uncertainty associated with the evolution of inflation we used an AR(1) model with an ARCH(2) structure of errors estimated by maximum-likelihood. Any GARCH structure tested was rejected. The model is indicated below and has 3 equations: equation (1) models the autoregressive for the inflation rate (π), equation (2) models the error term, where ϵ has a normal distribution (0,1), and equation (3) models conditional variance.

$$(1) \pi_t = \beta_0 + \beta_1 \pi_{t-1} + \mu_t$$

$$(2) \mu_t = \sigma_t \cdot \epsilon_t \quad \epsilon_t \sim N(0,1)$$

$$(3) \sigma_t^2 = \alpha_0 + \sum_{j=1}^2 \alpha_j \mu_{t-j}^2$$

Table 6. ML-ARCH(2) 1971:2-2010:4 (T = 159)

D4LIPC	Coefficient	std. error	Z	p-value
Constant	0.00167751	0.00116407	1.441	0.1496

alpha(0)	6.32146e-05	1.51812e-05	4.164	3.13e-05***
alpha(1)	0.384639	0.137367	2.800	0.0051***
alpha(2)	0.615361	0.147744	4.165	3.11e-05***

Log-likelihood 442.7605

Likelihood ratio test for (G)ARCH terms: Chi-square(2) = 85.5511 [2.64738e-19]

The estimated model (Table 6.) allows us to calculate the conditional variance and to analyse what happened in terms of uncertainty (Figure 2).

Figure 5. Conditional Variance Errors and Squared Root Associated to Inflation

Source: INE and authors' calculation based on model (1)-(3)

As we can see (Figure 5.), we can split uncertainty path into two periods: from 1970 to 1990 and from 1990 to 2010. This evolution is interpreted in terms of monetary policy change and credit market operations. The interest rates begin to decrease in a persistent way (Figure 6) after that year. The consequences were obvious: a huge real growth of monetary aggregates, the real annual growth rate of M1 from 1997:1 to 1999:4 was between 10.4% and 18.3%. Notice also that never in the past Portuguese individuals and firms had known such low values for the interest rates.

Figure 6. Short-run interest rate (bank lending to non-financial firms from 6 months to 1 year)

Source: Banco de Portugal, Boletim Estatístico.

Nominal interest rates were divided by 4 and real interest rates by 5 in 10 years (Table 7.). This was a sudden change, and no one, individual or firm, could resist to it.

Table 7. Short run interest rates (quarterly averages)

Years	Nominal (%)	Real (%)
1990 - 1991	23.1	10.3
1995 - 1996	12.1	8.2
1999 - 2000	5.3	2.6
2000 - 2001	5.8	2.1

Source: Banco de Portugal, Boletim Estatístico. Authors' calculation

As mentioned before, Portuguese inflation convergence towards the level of that of the European countries group with the lowest inflation was the result of a real exchange rate

appreciation policy. At the same time the process of financial integration had also an enormous impact on Portuguese macroeconomic disequilibrium's. At December 1992 financial transfers with the EU were totally liberalized by the initiative of Braga de Macedo, the Finance Minister. Current account exchange rate transfers were allowed for Europe only in 1964. Liberalization of capital movements, access to a massive market supply of funds, in a context of decreasing inflation expectations and reduced inflation uncertainty, resulted into an impressive reduction of interest rates, a sustainable decrease of domestic savings and into a continuous increase of internal and external indebtedness. This situation has originated a kind of Dutch disease.

The concept of Dutch disease was created in *The Economist* (1977) and the seminal papers are two: Corden and Neary (1982) and Corden (1984). Meanwhile, other sources have been envisaged to explain the so called disease: external remittances Edsel (2010), international aid Rajan and Subramanian (2011) and Verbeke (2007) and the phenomena of real exchange rate appreciation Adam (2005) and UNCTAD_(South_Centre) (2007). In what concerns Portuguese net transfers from EU, they reached 2.6% of GDP in 1996-99 and they decreased ever since : to 1.5% in 2004-07 and 1.3% in 2008-10. This aid was applied mostly in infrastructure investments. A majority of papers supports the idea that public investment has a positive effect on long-run output, Aschauer (1989) and Easterly and Rebelo (1993). However the estimated effect is often small or negligible and too much dependent on the methodologies employed Turrini (2004)). Afonso and St.Aubyn (2008) have concluded for the period 1960-2005, that Portuguese public investment has not a crowding out effect on private investment but at best the effect is not different from null in terms of 95% confidence intervals. And its total rate of return is negative for Portugal (as well as for Austria, Finland, Greece and Sweden). We can conclude that the policy of real exchange rate appreciation, EU structural funds and an impressive reduction of interest rates, all these together were major sources of the Portuguese *Dutch disease* that explain its spread that manifested mainly into an accruing indebtedness and lack of external competitiveness of the Portuguese economy.

5. Saving and indebtedness in the Portuguese economy

The intertemporal constraint of individuals and firms was very much relieved. With a rate of interest increasingly lower than the rate of time preference, why would individuals continue to save?

When we compare the saving rate (the ratio of National Saving to GDP) of Greece, Ireland and Portugal, since 1990 until 2008 we see that Ireland has maintained reasonable values of savings while Greece and Portugal after 1994 have reduced continually their savings (Bação and Duarte (2011)).

Figure 7. Ratio of national savings for Greece, Ireland and Portugal

Source: Ameco and authors' calculation

As it can be observed (Table 8.) the low level of savings for Greece and Portugal represent a clear indication that future problems to debt payments might occur, most probably.

Tabel 8. National Saving ratio of GDP

S/Y (%)	Greece	Ireland	Portugal
1973-73	33.4	20.9	29.4
1989-90	17.9	16.2	22.7
2009-10	2.9	10.9	8.7

Source: Ameco and authors' calculation

The low value of savings is the other side of the Portuguese external current account disequilibrium. It is clear that for Portugal we have also a twin's deficit problematic (Feldstein (1999)) with adverse effects on real exchange rate that affect both external competitiveness and growth of the Portuguese economy.

The low value of Portuguese savings was considered normal in the earlier years of its integration in EU, it was the consequence of a process of capital integration in a more developed area (Blanchard and Giavazzi (2002)) but some time later, it was taken as an indicator of a serious external imbalance (Blanchard (2007)).

The level of debts in the Portuguese economy has grown without any relation with the growth of output or incomes. Real growth rates (deflated by GDP implicit price level) and the ratios of indebtedness for general government, financial and non-financial corporation and households and assets of the rest of the world (RW) are shown in Table 9.

Table 9. Total liabilities of Portuguese institutional agents and RW Assets (%)

Source: Boletim Estatístico, Banco de Portugal. Financial Accounts. Authors' calculation. ST: short term securities other than shares excluding derivatives + financial derivatives + short term loans + trade credit and advances. LT: long term securities other than shares excluding derivatives + long term loans. The first two columns are real growth rates. The GDP implicit price index was used to deflate the nominal series.

The average annual growth rate of total debt for the period 1995-2007 was almost 9%. However this situation is far from the situation of Mexico in 1994-95, East Asia in 1997-98 and Russia and Brazil in 1998-99, Dadush, Dasgupta and Ratha (2000) and McCauley and Zukunft (2008) since short-term assets of the Rest of World were only 19% in 2010, last columns, (see also Essaadi, Jouini and Khallouli (2009)).

The growth of total long-term debts is 2.5 greater than that of short-term and in levels, long-term debt is more than 4 times the level of short-term debt. Even in 2008-2010 debts growth in the Portuguese economy was considerable. The last column shows the fragility of the Portuguese economy; from 1996 to 2010 the level of indebtedness was multiplied by 2.5. This indebtedness growth is incompatible with the sluggish evolution of the economy (see section 3).

The ratio to GDP of total debt from abroad has grown 4 times from 1996 to 2010 and the average real growth of debt from 1997 to 2001 was 20%. In Table 10. presents debt securities by by sources of institutional debtors. The Government is the most important debtor even if its position has been decreasing since 2005. The most recent reduction, for 2010, is naturally due to increasing

difficulties to sell securities abroad and also to of-budgets expenditures (see below). Actually it is difficult to say what has really happened: the debts of the financial institutions reflect the growing need for funds to buy public debt and a not negligible part of other residents' debt are debt of public firms or guaranteed by the State.

Table 10. International investment position: institutional debtors of securities

	1997	1998	1999	2000	2001	2002	2003

6. External Competitiveness of the Portuguese economy

In the second half of 1980, Pierre Bérégovoy, French finance minister and later primer minister, advocated the idea of competitive disinflation Lordon (1998) and Boissieu and Pisani-Ferry (1995). It was recognized that with irrevocably fixed exchange rates an economy would be more competitive if its inflation rate was lower than that of its competitors. That idea has never been considered by Portuguese policy makers. Figure 8. express what happened in terms of implicit prices, dividing the Portuguese series by the German series (A), and in terms of the real effective exchange rate (B).

Figure 8. Relative implicit prices and real effective exchange rate for Portugal Vs Germany

Source: Ameco. Real effective exchange rates, based on unit labour costs (total economy) :- Performance relative to the rest of the former EU-15, double export weights and authors' calculation

The implicit price level of Portuguese GDP measured in Euros has an increasing trend in relation to German implicit prices. This evolution of relative prices is an incentive to imports and a disincentive to exports. This same evolution is confirmed by the evolution of the real exchange rate. From 1986 to 2010 the Portuguese implicit real effective exchange rate suffered a real appreciation of 100% in terms of Germany values. And from 2000 to 2010 the appreciation was also high, 20%. This last result was also confirmed in Alexandre, et al. (2009) How can an economy with a technological level that is far from the technological leaders resists to this evolution? The obvious

consequence of this loss of external competitiveness was the external current balance disequilibrium and also the low level of savings and a sluggish output evolution.

“Portugal’s share in the world exports, particularly in goods, has substantially shrunk since the early nineties; also, compared to 1990, unlike the majority of the other EU member states, the ratio of exports of goods and services to GDP was reduced, and in 2005, well below EU averages” (p.53) Silva (2008). Even if “exports of goods are shifting from low to medium (low and high) technology products; traditionally uncompetitive products of textiles, clothing and footwear have significantly lost weight in the total” Silva (2008) (p.53). For Amaral (2006), Portugal in the second half of the nineties has suffered from the greatest negative shock in peacetime resulting from the emergence of countries such as China and India and the EU membership of Eastern European countries. In the absence of structural transformations Portugal (like Italy) was very vulnerable to those competitors, “Italy and Portugal entered EMU with industrial structures that placed them directly in China’s line of fire.”, Ahearne and Pisani-Ferry (2006), p.4. In this international setting of free movement of goods, the worst that could happen at the national level was a real exchange rate appreciation, and indeed it occurred.

7. Labour market and unemployment behaviour

Perhaps the best way to characterize the Portuguese labour market is to consider it as an apartheid situation, Eatwell (2010). The definition in CEU (2011) suits very well to Portugal labour market, “large differences in relative levels of employment protection legislation contributes to a division between well-protected workers with permanent contracts and less-protected workers with atypical, mostly temporary, contracts. The impact of the crisis has highlighted this issue: job losses for workers in temporary work were almost four times higher than for those in permanent employment.” (p.11)

During the last years the Portuguese labour market has experienced a downward trend of the OECD EPL index (Employment Protection Legislation) like some others economies in the European Union. In 2008 the Labour Code was revised and some measures were taken in order to facilitate its application by reducing procedural court processes, increasing trial periods and also reducing notice time and compensation for no-fault dismissal (OECD (2010)). The effects of these changes coincided with unemployment rate increase so the results of these changes have to be analyzed with caution.

Table 11. Unemployment rate for several countries

	2000	2010
EU – 27	8.7	9.6
Euro Area	8.5	10.1
Ireland	4.2	13.7
Greece	11.2	12.6
Spain	11.1	20.1
Portugal	4.0	11.0
Austria	3.6	4.4
U.S.A.	4.0	9.6

Source: Eurostat

The worst situations in terms of unemployment rate increases are reckoned by Portugal and Ireland, (Table 11). The unemployment rate from 2000 to 2010 was multiplied by 3. The unemployment rate for Austria is in 2010 the value of that rate in 2000 for Portugal and Ireland.

Historically, the unemployment rate in Portugal is not very different from that of the USA, but two differences are hidden in those numbers Blanchard and Portugal (2001). The duration of unemployment in Portugal is three times that of the USA and the relative flow of workers into unemployment in the USA is three times that of Portuguese workers.

In Figure 9. (A) and (B) we present total unemployment rate and the unemployment rate for workers with less than 25 years old (A) and the logs of the actual number of unemployed and the

unemployed by at least 25 months (B).

Figure 9. Unemployment Rate (A) and Unemployment Duration (B)

Source: INE. In (B) we have logs of workers in thousands.

Unemployment rate path exhibits three main characteristics: its increase after 2002 (A) with the youth unemployment rate increasing more than the total rate (A) and the increase of long duration unemployed workers (B).

The employment/unemployment data is obtained by inquiry based on Census (made every 10 years). This mean that during the 1990's the immigration from Latin America (Brazil), ex-Portuguese Colonies and Eastern European countries were actually on the labour force supply but were not reflected into the Employment Inquiry. In 2006 the total labour force supply was 5 601.4 thousands by the Inquiry and the immigrants were 437.126 thousands, 7.8% of the official value of the labour supply, Peixoto and Sabino (2009). As a consequence the actual unemployment rate was then lower than the official rate. Moreover, as Portugal is traditionally an emigration country this has also consequences on its unemployment rate. Portugal had three waves of emigration since 1850: at the end of XIX century, the second and biggest one in the 1960's and the third beginning in 2002, Pereira (2001). The European Union with the freedom of people circulation has created a problem for migration statistics in Portugal. Based on Pereira (2010) calculations the emigration was 108388 and 101595 in 2007 and 2008, respectively and from 2002 to 2008 the total value was 542 808. The present wave differentiates from the two previous waves by the higher education level of the new Portuguese emigrants, what represents an effective brain drain Pereira and Lains (2010). If at the end of 2010 we count these emigrants since 2002 as unemployed searching an employment, the unemployment rate 11.1% is underevaluated, it ascends to 18.9%, instead. The emigration phenomenon is known in Portugal as an "exhaust valve", as is confirmed by this calculation. The unemployment rate can be a bad indicator of the output gap as well as a bad social welfare indicator. We can conclude that the sluggish growth of the Portuguese economy has terrible effects in terms of unemployment.

8. Bad Governance: the problem of off-budgeting practice matters

Voters may not understand the significance of many forms of off-budget expenditures but not capital markets. For example, Amaral (2011) has stressed the inexistence of specific laws for public foundations. The government does not know the exact number of these institutions but they are dependent of public funds, as indeed private foundations. The XIII and XIV constitutional government of António Guterres (1995-2002) created many institutes with financial and administrative autonomy with the aim of making more efficient public decisions fleeing the constraints of state bureaucracy. Some years after a really parallel state structure were in place. A part of their receipts is off-budget and their liabilities are not aggregated in the general government

accounts. The debts of public and semi public firms created by central and local public administrations are guaranteed by the state but are not aggregated at the national public debt. The accumulated debt of non-financial firms owned by the state at the end of 2009 was 24.3% of the GDP, and in 2010 it is approximately 26%, Pereira (2010).

In the last years, public-private partnerships at the level of road and rail infrastructure and also hospital buildings and the associated production of health services became a very controversial subject. PPPs are an alternative to traditional public investment; they allow to keep these expenditures off-budget and to postpone the payment to the PPP operator in a yearly basis, Turrini (2004). This practice can hide inefficient projects and future commitments that are kept aside from the voters. Some of these contracts were renegotiated but always with more charges incurred by the State. Based on 2009 as reference year (Finanças (2010)), Table 12. shows the future costs from PPP. As we can see these costs represent with reference to 2010 1% by year of GDP. From 2011 to 2030 the total cost will be 20.9% of 2010 GDP, which is a huge amount of expenditures. The report for 2010 (Finanças (2011)) doesn't publish the future costs of PPP.

Table 11. PPP future costs in % of GDP (2010)

5 Years Period	% GDP 2010
2011-15	5.1
2016-20	6.5
2021-25	5.1
2026-30	4.2

Source: Finanças (2010) and authors' calculation

More important than public debt level is the absence of credible information about State liabilities, direct or indirect, like future liabilities associated to PPP expenditures already discussed that endangers capital markets confidence on Portuguese economy.

And finally we want to stress recent opportunist policies in a context of fiscal consolidation. The dates of recognition of an excessive deficit and for abrogating that decision were: 2002-04, 2005-08 and 2009-? (see for Portugal EC (22.6.2005), EC (2005), EC (7.10.2009) and EC (11.11.2009). For all the excessive deficit processes: EC (2011)). In 2008, using the data then recognized by Portugal and Eurostat, Portugal exit an excessive deficit situation by implementing rigorous control of public expenditures and receipts. Political measures such as TVA reduction from 21% to 20% (30th May 2008) and public sector wages increase of 2.9% in 2009 due to elections to the Portuguese parliament, European Parliament and local governments were important signs that fiscal consolidation was no more a Government priority.

Conclusion

We have portrayed Portuguese economy tracing a general picture whose main characteristics are a situation diagnosed as a kind of Dutch disease since the second half of the 1990's, with a systematically decrease of its savings and suffering from the impact of globalization and loss of external competitiveness followed from a stagnated output since 2002

We have also concluded that the output gap and the unemployment rate have to be interpreted carefully. A new output trend was calculated in order to correct the recent actual Portuguese sluggish growth. The third vague of emigration has reduced the actual labour supply value resulting in the decrease of the unemployment rate. Besides that high unemployment rates express a situation of apartheid in the labour market and low skills of older workers.

A sluggish growth means less budget receipts and the government reaction to this was the development of an off-budget practice and also the creation of public firms to hide the increased disequilibrium between expenditures and receipts. The development of a parallel government structure, with the creation of public firms at the central and local governments, to employ party elements and pay them out of public administration salaries has also contributed to a real problem of lack of transparency and accountability. Why would international financial markets and rating agencies ignore this situation and these facts?

The Portuguese problems will be solved only with output growth. The simpler rule for inter-temporal budget constraint states that debt can only be sustainable if real output growth is greater than the real interest rate. With an interest rate of 5.1 (more or less the average of the financial aid to the Portuguese economy), output has to grow at a minimum of 3%. This is the real challenge for the Portuguese economy.

- John T. Addison, Paulino Teixeira, Alex Bryson & André Pahnke
- 2011-14 *Are health factors important for regional growth and convergence? An empirical analysis for the Portuguese districts*
- Ana Poças & Elias Soukiazis
- 2011-13 *Financial constraints and exports: An analysis of Portuguese firms during the European monetary integration*
- Filipe Silva & Carlos Carreira
- 2011-12 *Growth Rates Constrained by Internal and External Imbalances: a Demand Orientated Approach*
- Elias Soukiazis, Pedro Cerqueira & Micaela Antunes
- 2011-11 *Inequality and Growth in Portugal: a time series analysis*
- João Sousa Andrade, Adelaide Duarte & Marta Simões
- 2011-10 *Do financial Constraints Threat the Innovation Process? Evidence from Portuguese Firms*
- Filipe Silva & Carlos Carreira
- 2011-09 *The State of Collective Bargaining and Worker Representation in Germany: The Erosion Continues*
- John T. Addison, Alex Bryson, Paulino Teixeira, André Pahnke & Lutz Bellmann
- 2011-08 *From Goal Orientations to Employee Creativity and Performance: Evidence from Frontline Service Employees*
- Filipe Coelho & Carlos Sousa
- 2011-07 *The Portuguese Business Cycle: Chronology and Duration Dependence*
- Vitor Castro
- 2011-06 *Growth Performance in Portugal Since the 1960's: A Simultaneous Equation Approach with Cumulative Causation Characteristics*
- Elias Soukiazis & Micaela Antunes
- 2011-05 *Heteroskedasticity Testing Through Comparison of Wald-Type Statistics*
- José Murteira, Esmeralda Ramalho & Joaquim Ramalho
- 2011-04 *Accession to the European Union, Interest Rates and Indebtedness: Greece and Portugal*
- Pedro Bação & António Portugal Duarte
- 2011-03 *Economic Voting in Portuguese Municipal Elections*
- Rodrigo Martins & Francisco José Veiga
- 2011-02 *Application of a structural model to a wholesale electricity market: The Spanish market from January 1999 to June 2007*
- Vítor Marques, Adelino Fortunato & Isabel Soares
- 2011-01 *A Smoothed-Distribution Form of Nadaraya-Watson Estimation*
- Ralph W. Bailey & John T. Addison
-
- 2010-22 *Business Survival in Portuguese Regions*
- Alcina Nunes & Elsa de Moraes Sarmento
- 2010-21 *A Closer Look at the World Business Cycle Synchronization*
- Pedro André Cerqueira
- 2010-20 *Does Schumpeterian Creative Destruction Lead to Higher Productivity? The effects of firms' entry*
- Carlos Carreira & Paulino Teixeira
- 2010-19 *How Do Central Banks React to Wealth Composition and Asset Prices?*
- Vítor Castro & Ricardo M. Sousa

-
- 2010-18 *The duration of business cycle expansions and contractions: Are there change-points in duration dependence?*
- Vítor Castro
- 2010-17 *Water Pricing and Social Equity in Portuguese Municipalities*
- Rita Martins, Carlota Quintal, Eduardo Barata & Luís Cruz
- 2010-16 *Financial constraints: Are there differences between manufacturing and services?*
- Filipe Silva & Carlos Carreira
- 2010-15 *Measuring firms' financial constraints: Evidence for Portugal through different approaches*
- Filipe Silva & Carlos Carreira
- 2010-14 *Exchange Rate Target Zones: A Survey of the Literature*
- António Portugal Duarte, João Sousa Andrade & Adelaide Duarte
- 2010-13 *Is foreign trade important for regional growth? Empirical evidence from Portugal*
- Elias Soukiazis & Micaela Antunes
- 2010-12 *MCMC, likelihood estimation and identifiability problems in DLM models*
- António Alberto Santos
- 2010-11 *Regional growth in Portugal: assessing the contribution of earnings and education inequality*
- Adelaide Duarte & Marta Simões
- 2010-10 *Business Demography Dynamics in Portugal: A Semi-Parametric Survival Analysis*
- Alcina Nunes & Elsa Sarmento
- 2010-09 *Business Demography Dynamics in Portugal: A Non-Parametric Survival Analysis*
- Alcina Nunes & Elsa Sarmento
- 2010-08 *The impact of EU integration on the Portuguese distribution of employees' earnings*
- João A. S. Andrade, Adelaide P. S. Duarte & Marta C. N. Simões
- 2010-07 *Fiscal sustainability and the accuracy of macroeconomic forecasts: do supranational forecasts rather than government forecasts make a difference?*
- Carlos Fonseca Marinheiro
- 2010-06 *Estimation of Risk-Neutral Density Surfaces*
- A. M. Monteiro, R. H. Tütüncü & L. N. Vicente
- 2010-05 *Productivity, wages, and the returns to firm-provided training: who is grabbing the biggest share?*
- Ana Sofia Lopes & Paulino Teixeira
- 2010-04 *Health Status Determinants in the OECD Countries. A Panel Data Approach with Endogenous Regressors*
- Ana Poças & Elias Soukiazis
